The List!

In a repl, code editor or in your browser console, create and name an array filled with items! Some ideas:

- A grocery list
- A list of Hogwarts students
- A list of Batman villains

1. In the code:

   - access the first element in your array

   - Add some more items using the unshift or push function

   - update a value from the third element in the array

2. Now, let's suppose that we need to use information from every single one of our items.

   How could we accomplish this?

   - What's one way to access every element in your array?

   - What are some drawbacks you can think of?
